PDFBLUR(1) PDFBLUR(1)

NAME

pdfblur - generate views for depth-of-field blurring

SYNOPSIS

pdfblur aperture nsamp viewfile

DESCRIPTION

Pdfblur takes the given viewfile and computes nsamp views based on an aperture diameter of aperture (in world coordinate units) and a focal distance equal to the length of the -vd view direction vector. When rendered and averaged together, these views will result in a picture with the specified depth of field. Either pinterp(1) or rpict(1) may be called to do the actual work. (The given viewfile must also be passed on the command line to the chosen renderer, since pdfblur provides supplemental view specifications only.)

For *pinterp*, feed the output of *pdfblur* to the standard input of *pinterp* and apply the -B option to blur views together. In most cases, a single picture with z-buffer is all that is required to get a satisfactory result, though the perfectionist may wish to apply three pictures arranged in a triangle about the aperature, or alternatively apply the -ff option together with the -fr option of *pinterp*. (The latter may actually work out to be faster, since rendering three views takes three times as long as a single view, and the -fr option will end up recomputing relatively few pixels by comparison.)

To use pdfblur with rpict, apply the -S option to indicate a rendering sequence, and set the -o option with a formatted file name to save multiple output pictures. When all the renderings are finished, combine them with the pcomb(1) program, using appropriate scalefactors to achieve an average. Note that using rpict is MUCH more expensive than using pinterp, and it is only recommended if the scene and application absolutely demand it (e.g. there is prominent refraction that must be modeled accurately).

For both *pinterp* and *rpict*, the computation time will be proportional to the number of views from *pdfblur*. We have found a *nsamp* setting somewhere between 5 and 10 to be adequate for most images. Relatively larger values are appropriate for larger aperatures.

The -pd option of *rpict* may be used instead or in combination with or instead of *pdfblur* to blur depth-of-field. If used in combination, it is best to set the -pd option to the overall *aperture* divided by *nsamp* to minimize ghosting in the output.

To simulate a particular camera's aperture, divide the focal length of the lens by the f-number, then convert to the corresponding world coordinate units. For example, if you wish to simulate a 50mm lens at f/2.0 in a scene modeled in meters, then you divide 50mm by 2.0 to get 25mm, which corresponds to an effective aperture of 0.025 meters.

EXAMPLES

To use *pinterp* to simulate an aperture of 0.5 inches on a lens focused at a distance of 57 inches:

```
rpict –vf myview –x 640 –y 480 –z orig.zbf scene.oct > orig.hdr pdfblur 0.5 57 8 orig.hdr | pinterp –B –vf orig.hdr –x 640 –y 480 orig.hdr orig.zbf > blurry.hdr
```

To use *rpict* exclusively to do the same:

```
pdfblur .5 57 5 myview | rpict -S 1 -vf myview -x 640 -y 480 -o view%d.hdr scene.oct pcomb -s .2 view1.hdr -s .2 view2.hdr -s .2 view3.hdr -s .2 view4.hdr -s .2 view5.hdr > blurry.hdr
```

AUTHOR

Greg Ward

BUGS

This program really only works with perspective views.
